Decision-time information in rolling airline recovery

An AOCC snapshot: the same delay signal can hide different operational exposure.

Part 1. AOCC decision-time state

One aircraft-linked predecessor-successor episode, observed before successor execution is complete.

Delay priority (P^D) similar predicted successor take-off delay

Chain A

context cues: turnaround buffer | aircraft continuity | downstream rotation — Flight emphasis

Chain B

context cues: passenger connections | downstream exposu | resource burden — Passenger / Resource emphasis

State-informed consequence priority (P^C)

The retained context can distinguish chains that look similar under (P^D).

Part 2. Stage I screening

Delay priority versus consequence priority under limited capacity

Which chains enter detailed recovery review?

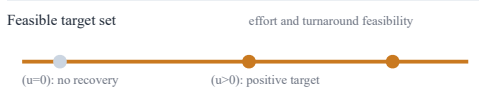

top-K shortlist is the active comparison.

Part 3. Stage II local recovery

For a shortlisted chain: (u=0) versus (u>0)

The target is selected under a consequence-effort objective.

Information value is observed through shortlist or target changes.
