Decision-time information in rolling airline recovery

Schematic AOCC snapshot: similar delay, different operational exposure.

Part 1. AOCC decision-time state

Two aircraft-linked chains assessed during turnaround.

Predecessor in-block — factual

Successor off-block — unresolved

Successor take-off — unresolved

Delay priority (P^D) similar predicted take-off delay

Chain A — TURN

- Turnaround buffer
- Aircraft continuity
- Downstream rotation

Chain B — TURN

- Passenger connections
- Downstream exposure
- Operating burden

State-informed Consequence (P^C)

Flight, Passenger and Resource consequences distinguish these chains.

Part 2. Stage I screening

Delay versus consequence-based priority

Which chains enter the limited review shortlist?

Delay priority (P^D) — similar delay-based priorities

Consequence (P^C) — context may change selection

Same candidates and capacity; different priority signals.

Part 3. Stage II local recovery

Within one shortlisted chain: u=0 or u>0

Compare consequences and effort across feasible targets.

Feasible target set — turnaround feasibility

(u=0): no recovery

(u>0): positive target

Information value depends on the supported decision.
