At the AOCC, delay is a baseline - not the decision

One decision-time view of two disrupted aircraft-linked chains.

1. Operating situation

Two chains compete for recovery attention.

Chain A
delay: similar — aircraft continuity

Chain B
delay: similar — passenger / downstream exposure

The baseline signal sees similar delay.
The operating context need not be similar.

2. Information retained

What the decision-time representation preserves.

Delay baseline
scalar severity
A and B appear close in priority

retain state distinctions

State-informed view
Flight | Passenger | Resource
A and B need not rank alike
decision-relevant consequence distinctions

Information has value only when it changes the active comparison.

3. AOCC decision

The same retained information supports two tasks.

Stage I: screening
compare priority across chains
limited review capacity - choose top-K

Stage II: local recovery
compare targets within one chain
effort and feasibility - activate or target

Recovery priority does not imply recoverability.
The supported decision determines the value of the information.
