# How operational information changes a recovery decision

An AOCC example: similar delay can carry different recovery implications.

## 1. At the AOCC

Two disrupted chains await recovery review.

decision epoch: PRE - TURN - TAXI

**Chain A**

same delay baseline

Flight / continuity

**Chain B**

same delay baseline

Passenger / downstream

Same delay signal.

Different operating context.

## 2. What the view retains

The difference is in the consequence composition.

**Delay alone**

A and B appear close in priority

retain operating context

**State-informed consequences**

schematic composition, not a measured scale

Chain A

Chain B

Composition differs; the active ordering may change.

## 3. What the AOCC compares

Same information, different decision layers.

**Screening**

across chains: A versus B

limited review capacity

**Local recovery**

within one chain: no recovery versus positive target

effort and feasibility

Information value is decision-specific.

Priority and recoverability are related, but not identical.
