An AOCC recovery decision unfolds in sequence

Illustrative scenario: two disrupted aircraft-linked chains have similar delay, but different operational exposure.

1. AOCC sees the disruption at one decision epoch

predecessor progress and successor conditions are only partly resolved

PRE — predecessor

TURN — turnaround

TAXI — successor

Chain A	similar predicted delay	tight turnaround
Chain B	similar predicted delay	passenger / downstream

2. Stage I: screening

Limited review capacity

Which disrupted chains enter detailed review?

candidate chains	priority comparison
Chain A — review candidate	top-K boundary
Chain B — review candidate	priority may reorder the shortlist

3. Stage II: local recovery for a shortlisted chain

Priority earns detailed review; it does not guarantee that a positive intervention is worthwhile.

Within one selected chain

compare feasible local-recovery targets

turnaround feasibility + recovery effort

no recovery — positive target — larger target

What the paper evaluates

Whether retaining operating distinctions changes the shortlist or the local-recovery target.

Information value is decision-specific.
