An AOCC recovery decision unfolds from operating context

Part 1 introduces the application problem; Parts 2 and 3 show the sequential decisions it supports.

Part 1. One AOCC decision epoch

Two disrupted successor chains have similar delay, but different operational exposure.

Observed delay baseline similar predicted successor take-off delay

Chain A

tight turnaround | aircraft continuity | same delay signal

Chain B

passenger connections | downstream exposure | same delay signal

Why delay alone is insufficient

A delay signal summarizes severity; the operating context determines which Flight, Passenger, and Resource consequences are decision-relevant.

Part 2. Stage I screening

Limited review capacity

Which disrupted chains enter detailed recovery review?

Part 3. Stage II local recovery

For a shortlisted chain

Priority earns detailed review; it does not guarantee positive recovery.

Compare feasible targets within one chain

turnaround feasibility + recovery effort

The supported decision determines information value.
